

WATER FLOAT SETUP GUIDE

For any questions and support, visit the Discord or you can email me directly at: *pathiralgames@gmail.com*

GETTING STARTED:

1. Add **WaterFloat** component to any gameobject you want.

2. Set the amplitudes and frequency. Amplitude is how high the gameobject will float while frequency is how fast it'll move.

3. If you would like to have rotation then make sure you add the rotation amplitudes and frequency as well. If you don't, then zero both.

4. Play and that's it! Your object now has a water floating effect

5. Now it's all about tweaking those properties we have and understanding them more.

PROPERTIES:

- **Amplitude** – How high or far the gameobject will move in the axis. The more the value is on any axis the more far/high the object will move on that axis.

- **Frequency** – This is the speed. This controls how fast the gameobject will move to the amplitude on each axis.

- **RotationAmplitude** – This is the maximum degree of rotating the gameobject. Take note: rotation is based on a sinewave so rotation goes back and forth.

- **RotationFrequency** - the speed of the rotation.
